The Big Picture

Thierry Sans

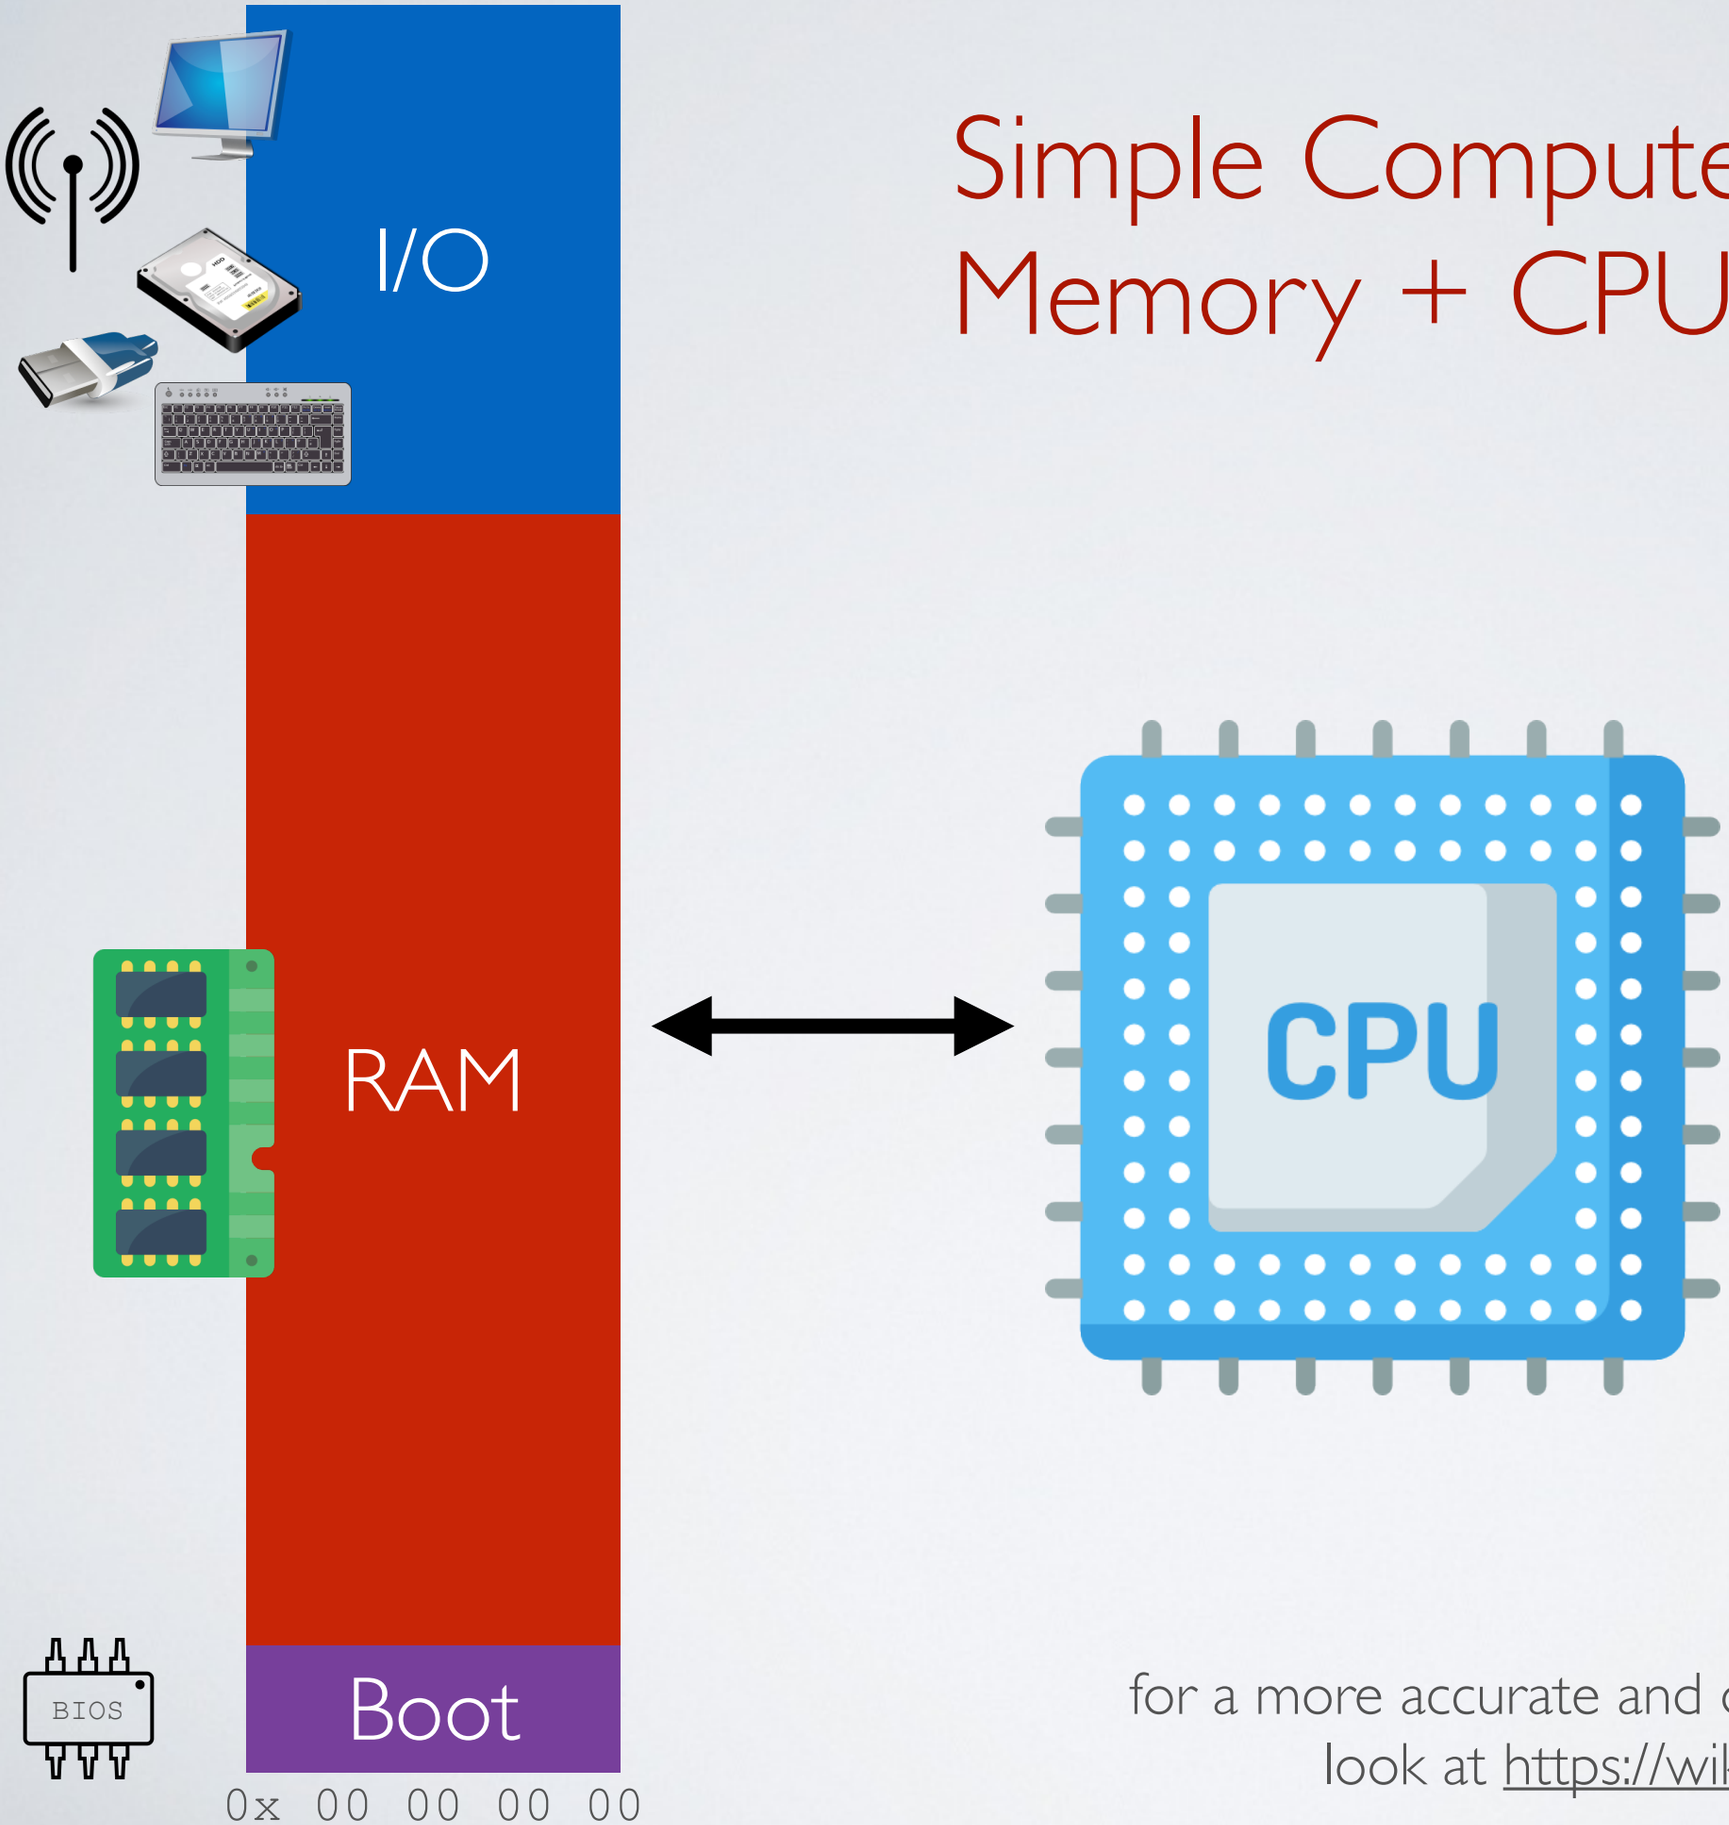
Goals of this lecture

- Define what an Operating System is
- Explain how an OS works in a nutshell
- Bridge the gap between hardware (CSCB58) and systems programming (CSCB09)
- Give an overview of the course content and projects

The big picture in 5 pieces

The need for **bootstrapping** and **system calls**	project 0
The need for **concurrency**	project 1
The need for **user spaces**	project 2
The need for **virtual memory**	project 3
The need for **a filesystem**	project 4

Simple Computer Architecture
Memory + CPU



for a more accurate and detailed map of the x86 memory
look at https://wiki.osdev.org/Memory_Map_(x86)

Each processor has its Instruction Set Architecture (ISA)

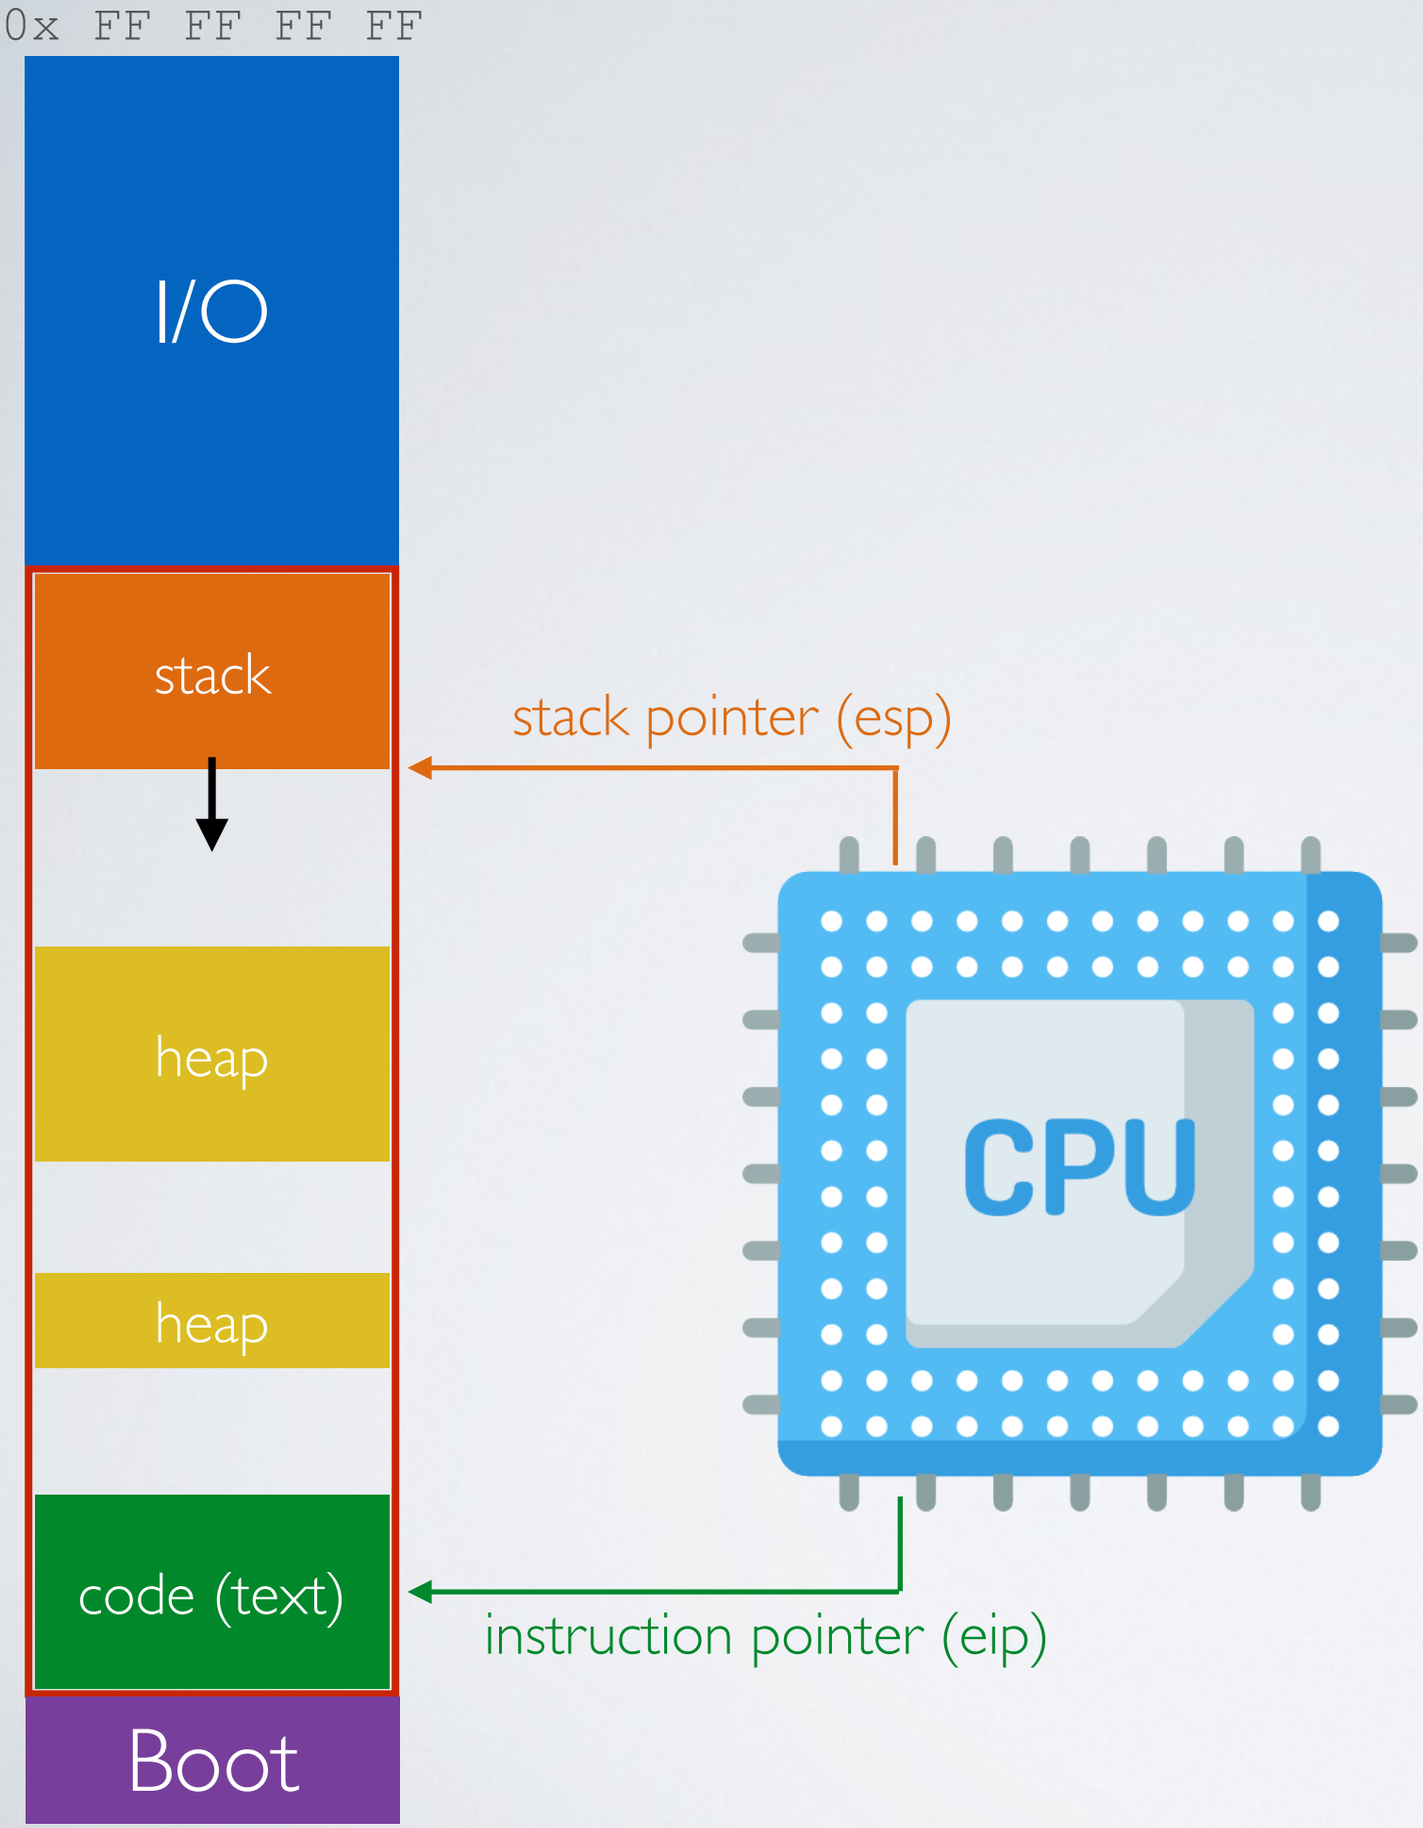
Processor executes instructions stored in memory

➡ Each instruction is a bit string that the processor understands as an operation

- arithmetic
- read/write bit strings
- bit logic
- jumps

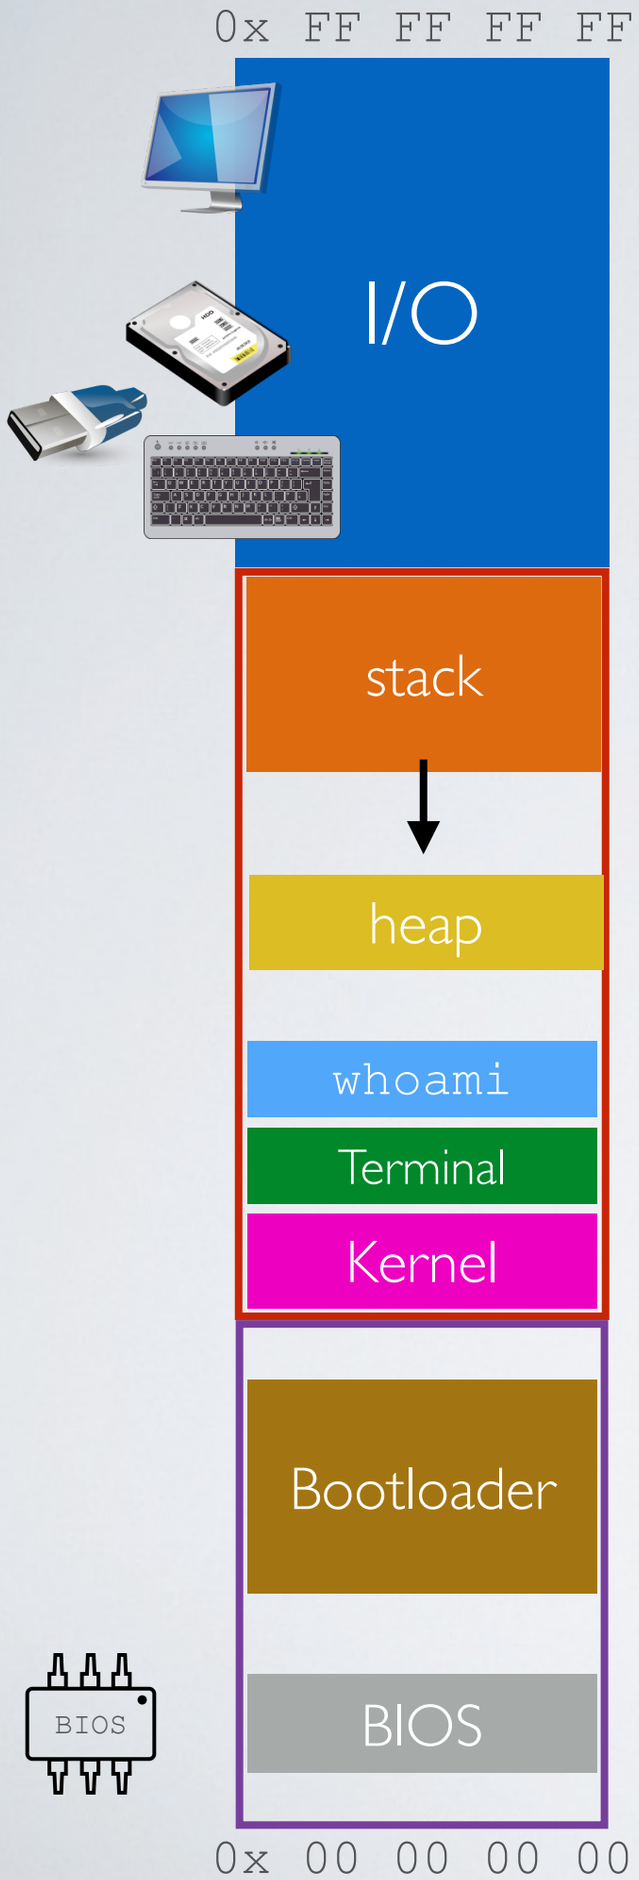
✓ ~2000 instructions on modern x86-64 processors

Running one program



The need for **bootstrapping** and **system calls**

Bootstrapping



Step 5: using the terminal, users can execute programs (e.g Bash terminal) ... and repeat

Step 4: the kernel starts the user-interface program (e.g `Bash` terminal)

Step 3: the bootloader loads the OS kernel in RAM

Step 2: the BIOS loads the **bootloader** from a device (hard-drive, USB, network ...) based on the configuration

Step 1: Power -on! The CPU starts executing code contained in the **BIOS** (basic input/output system)

The need for abstraction for user programs

How to write a user program like the *Bash* shell that reads keyboard inputs from the user?

➡ Read input data from the I/O device directly? But which one?

- The one connected to the PS2 port?
- The one connected to the USB?
- The one connected to the bluetooth?
- The remote one connected to the network?

◉ User programs do not operate I/O devices directly

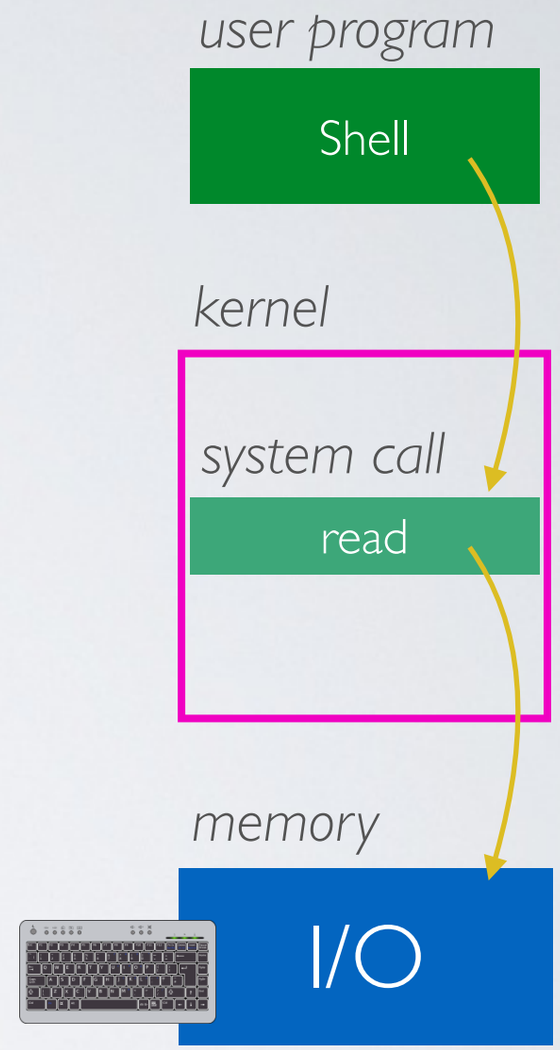
✓ The OS abstracts those functionalities and provide them as **system calls**

System Calls

➡ Provide user programs with an API to use the services of operating system

There are 5 categories of system calls

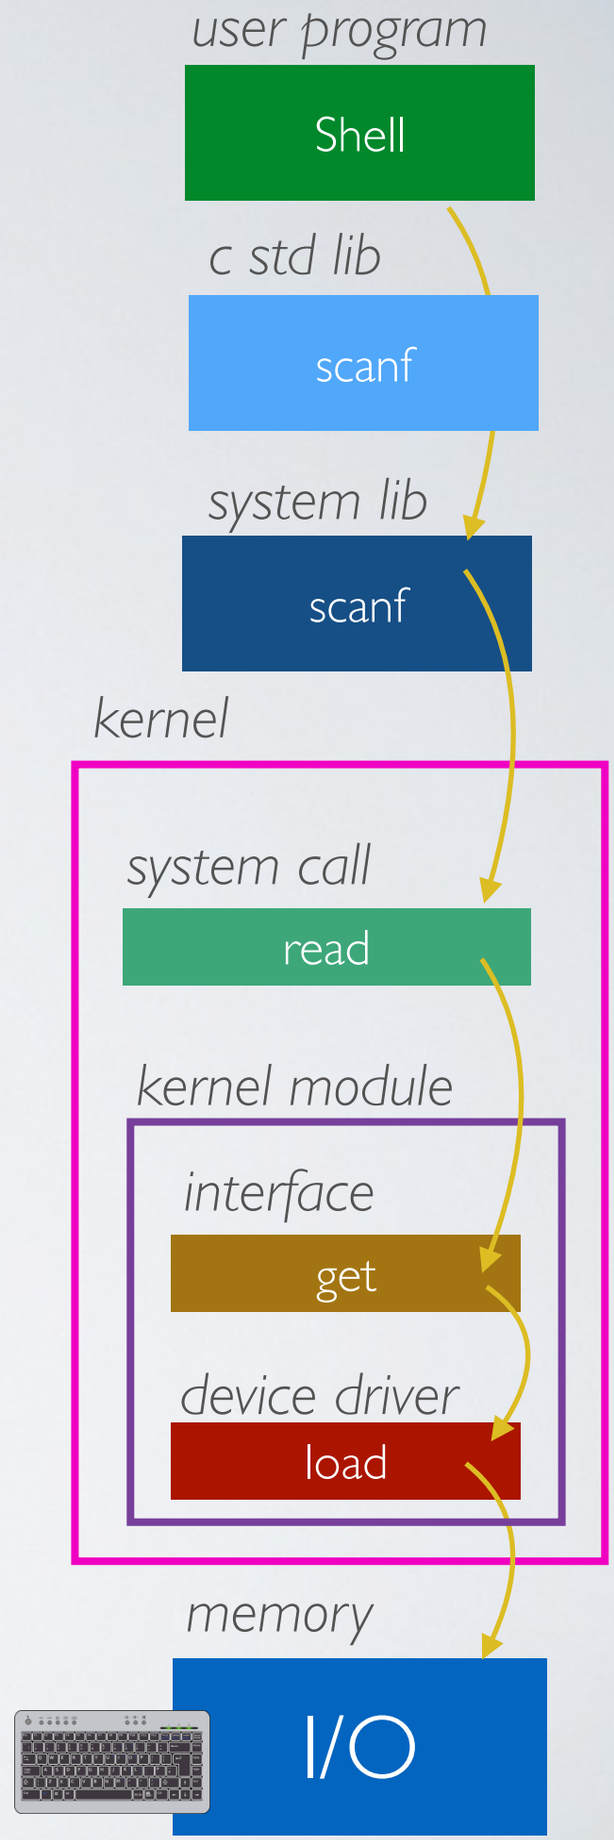
- Process control
- File management
- Device management
- Information/maintenance (system configuration)
- Communication (IPC)
- Protection



✓ There are 393 system calls on Linux 3.7

http://www.cheat-sheets.org/saved-copy/Linux_Syscall_quickref.pdf

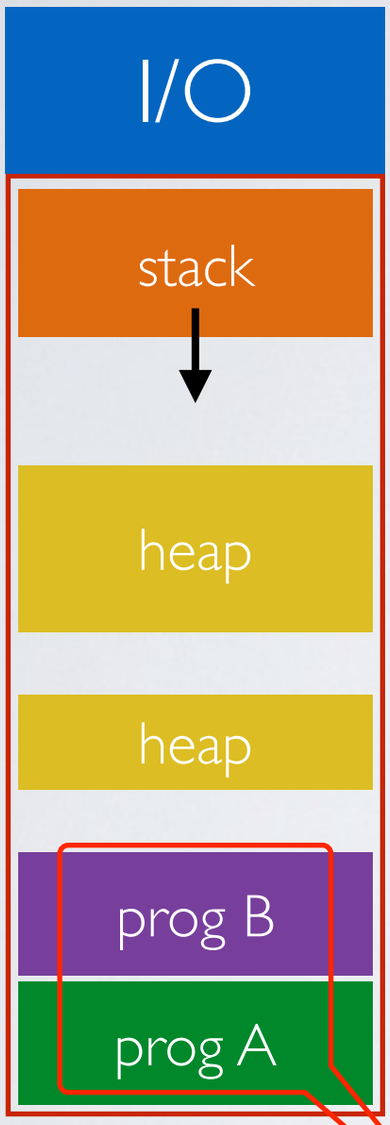
In reality, many (many) level of abstraction and modularity



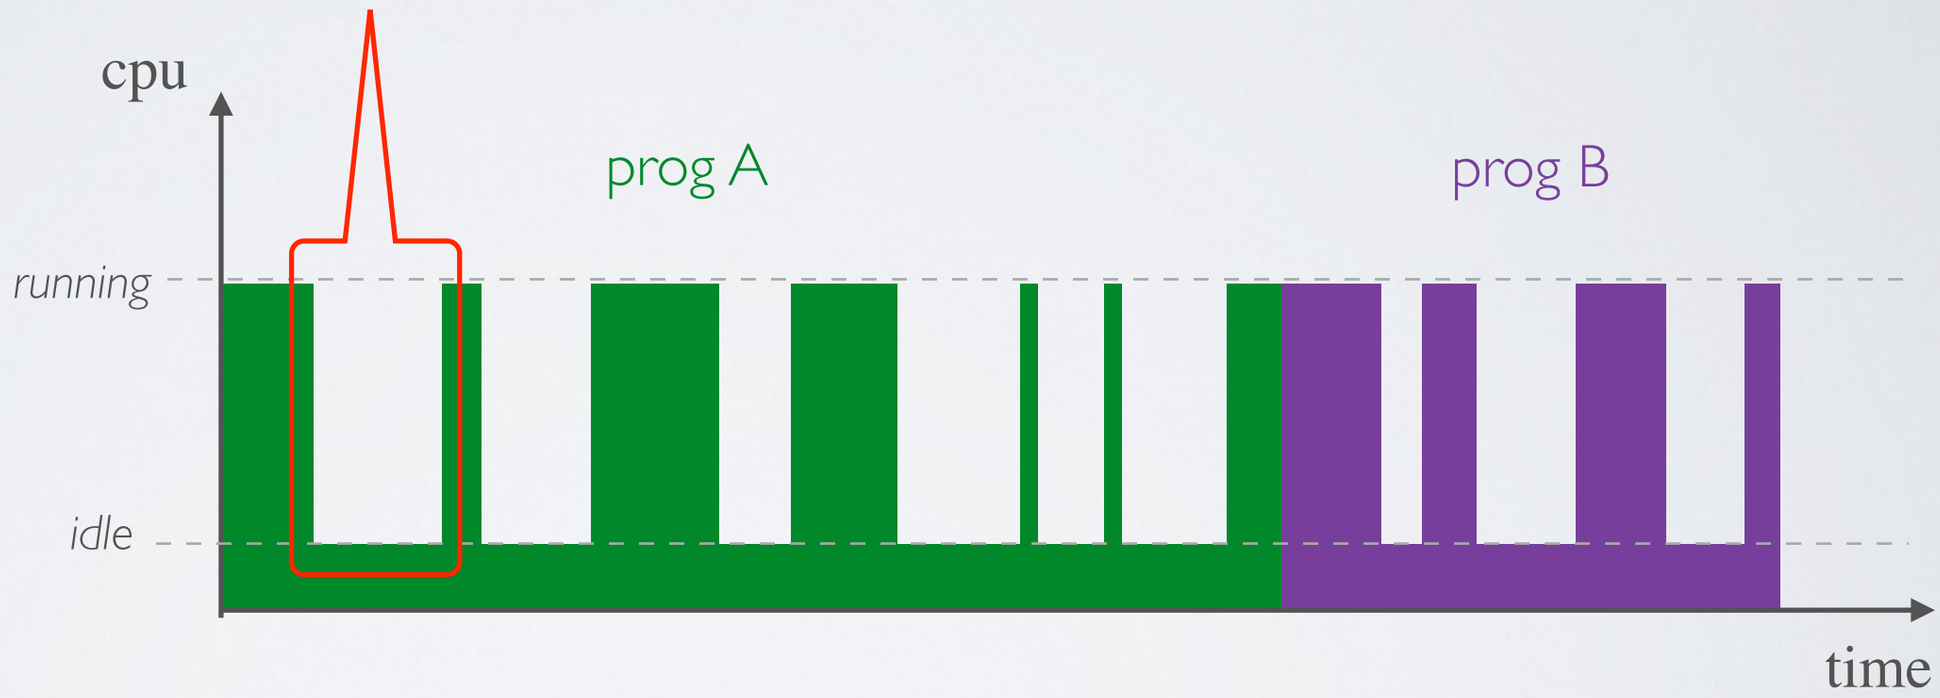
- This is what makes developing OS very challenging (CSCB07)

The need for **concurrency**

Running multiple programs one after the other

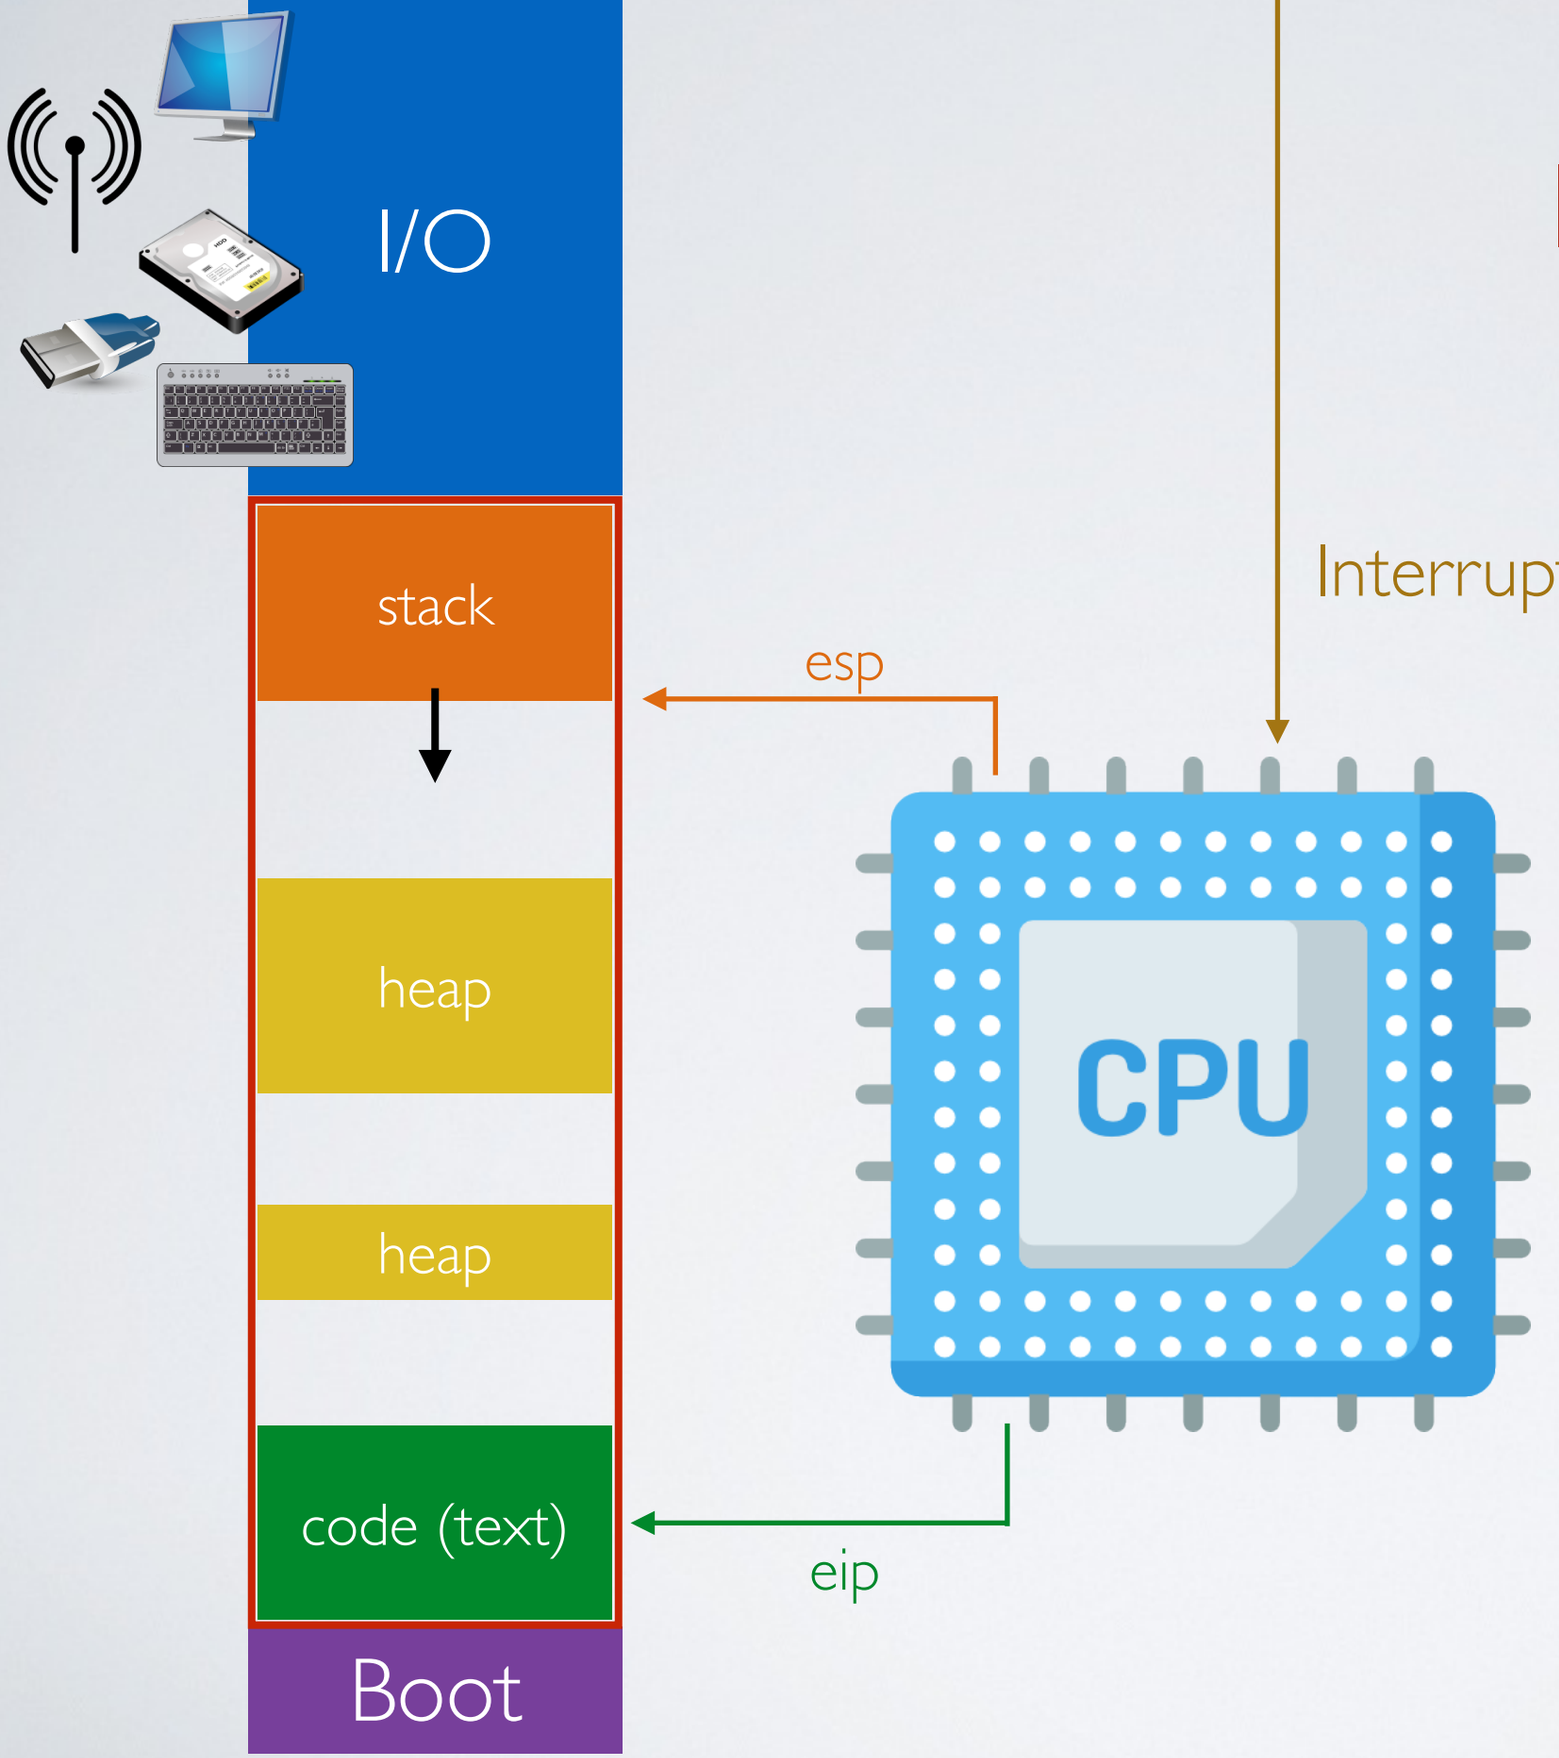


Problem: the CPU is waiting for I/O (polling)



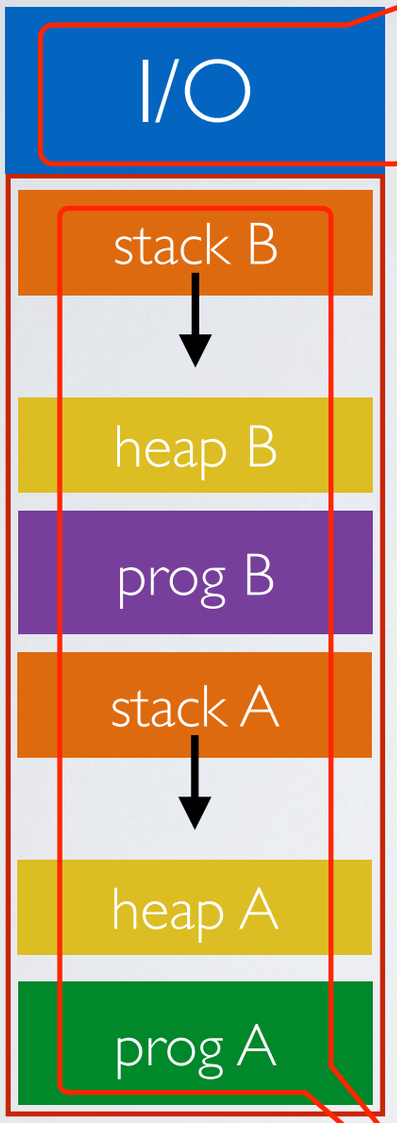
Problem: the programs must co-exists in memory (coming next with virtual memory)

I/O with interrupts

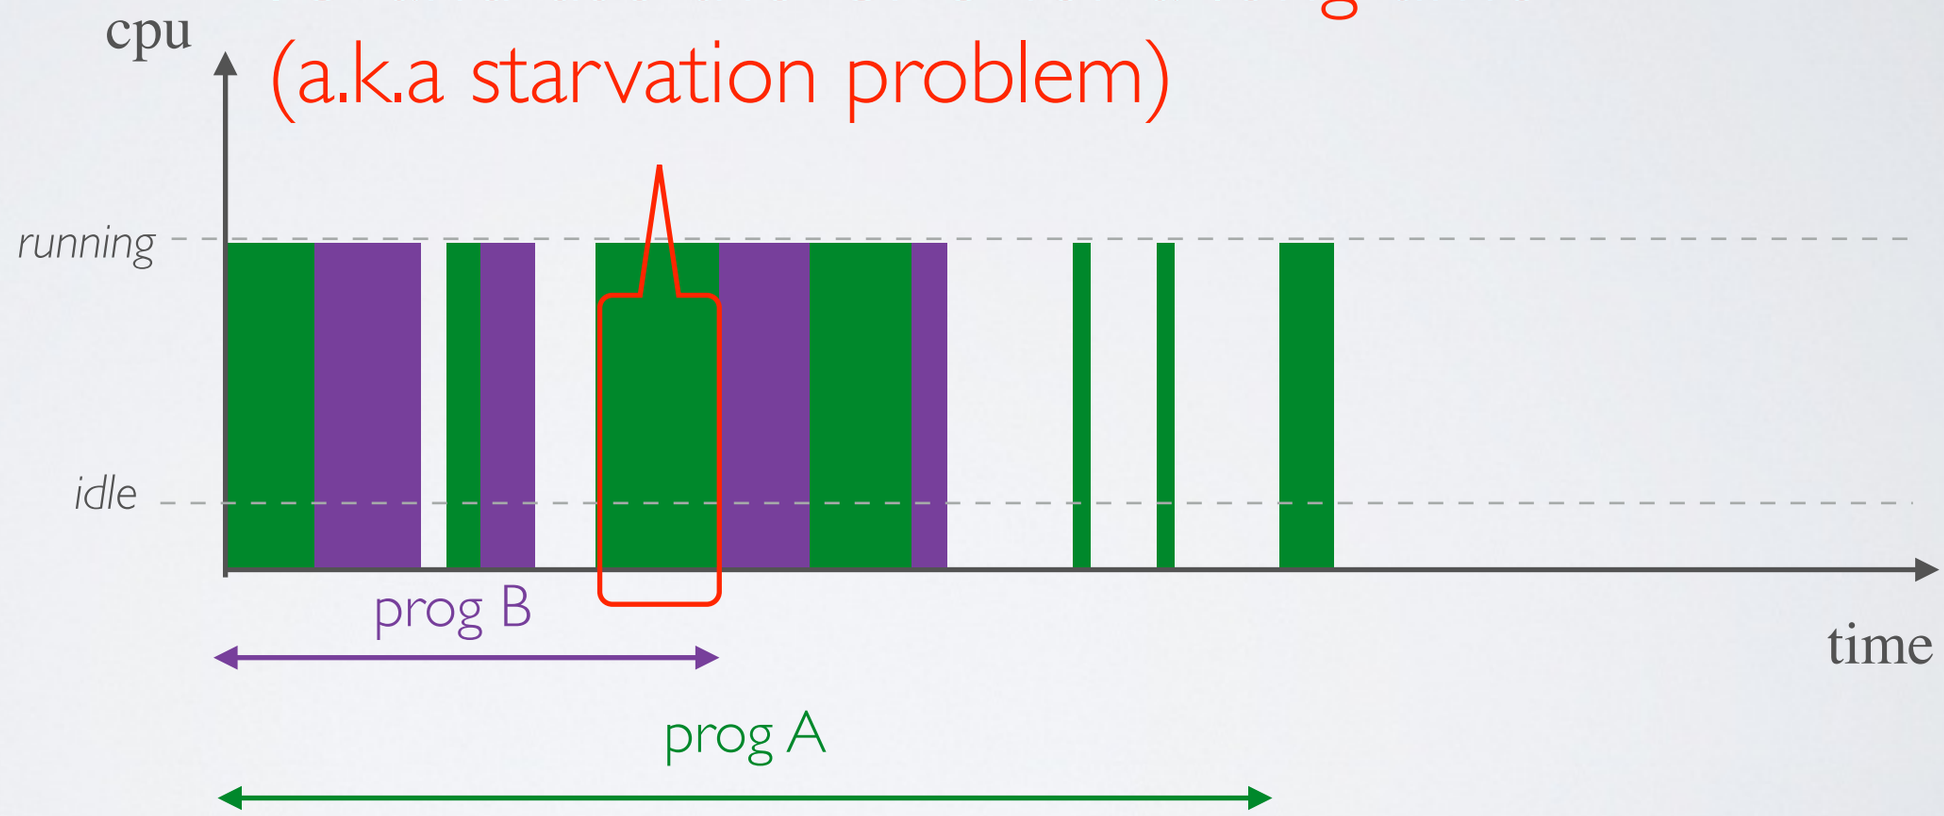


Running multiple programs concurrently

Problem: concurrent access to I/O devices must be synchronized

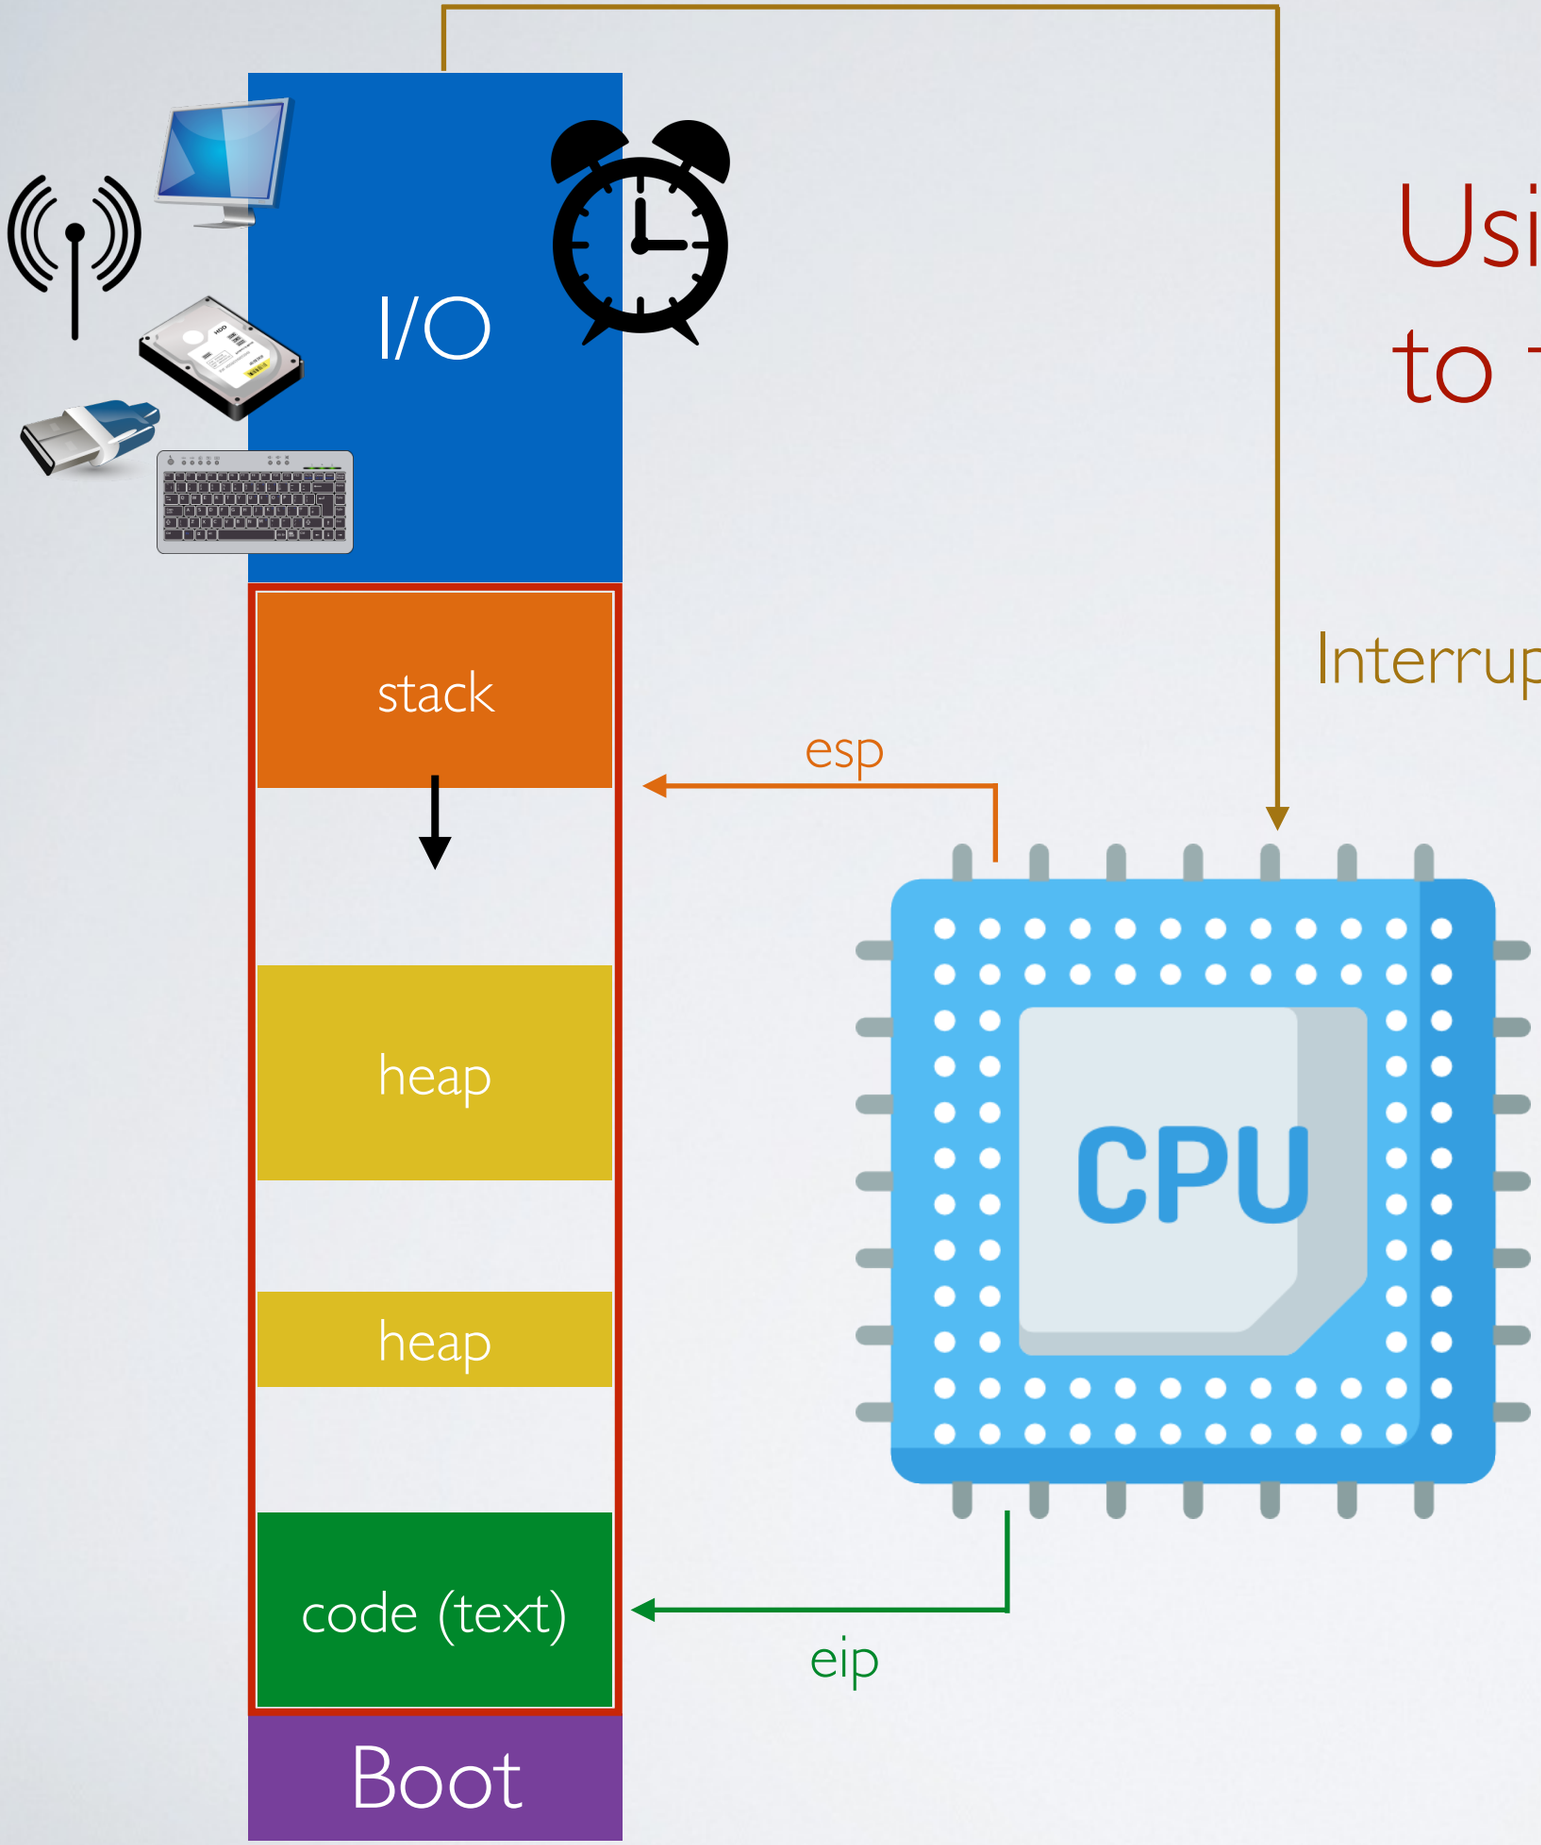


Problem: what if the program does not do any IO and use the CPU for a long time (a.k.a starvation problem)

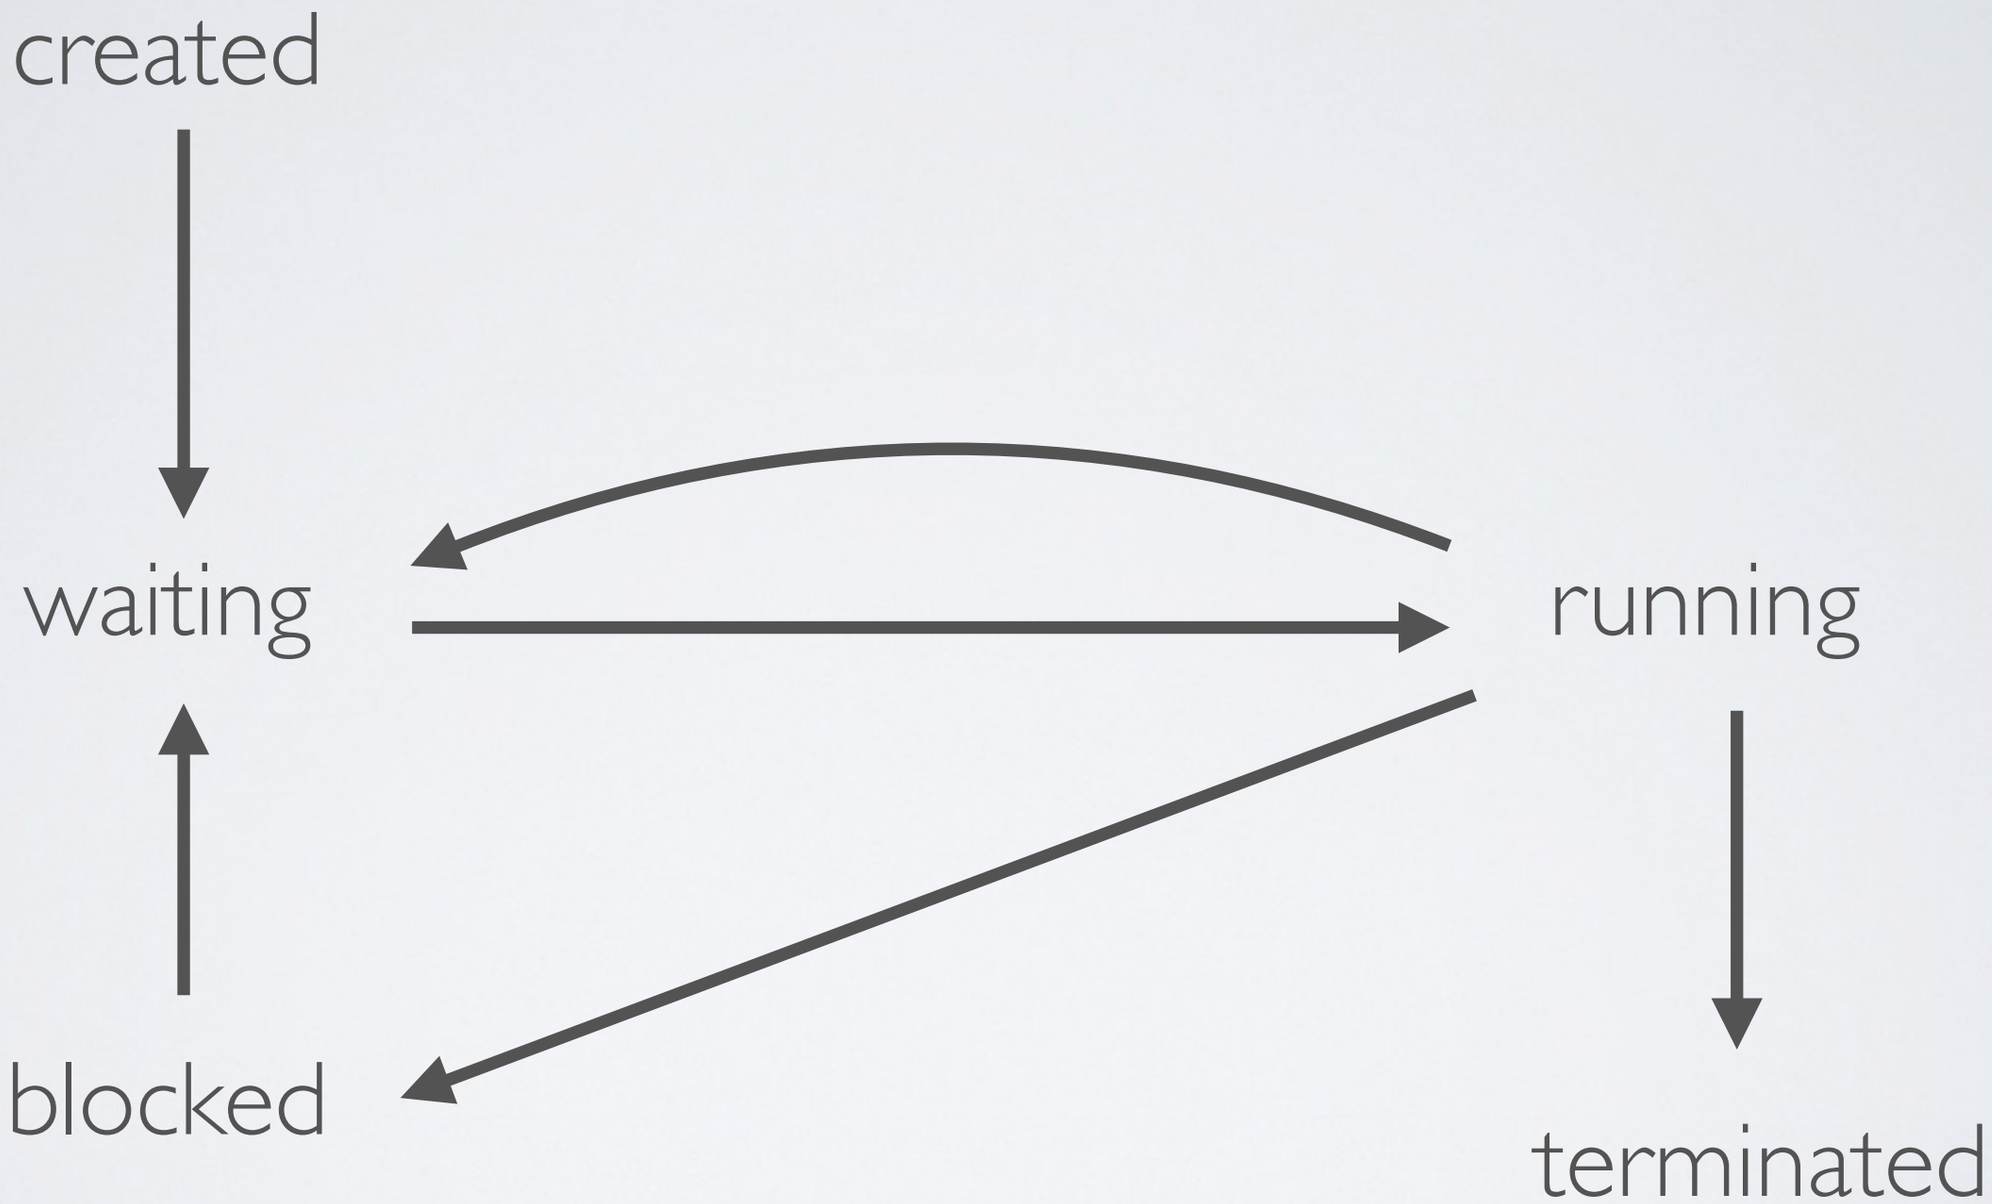


Problem: the programs and their stacks must co-exists in memory (coming next with virtual memory)

Using the clock to trigger an interrupt



Process States



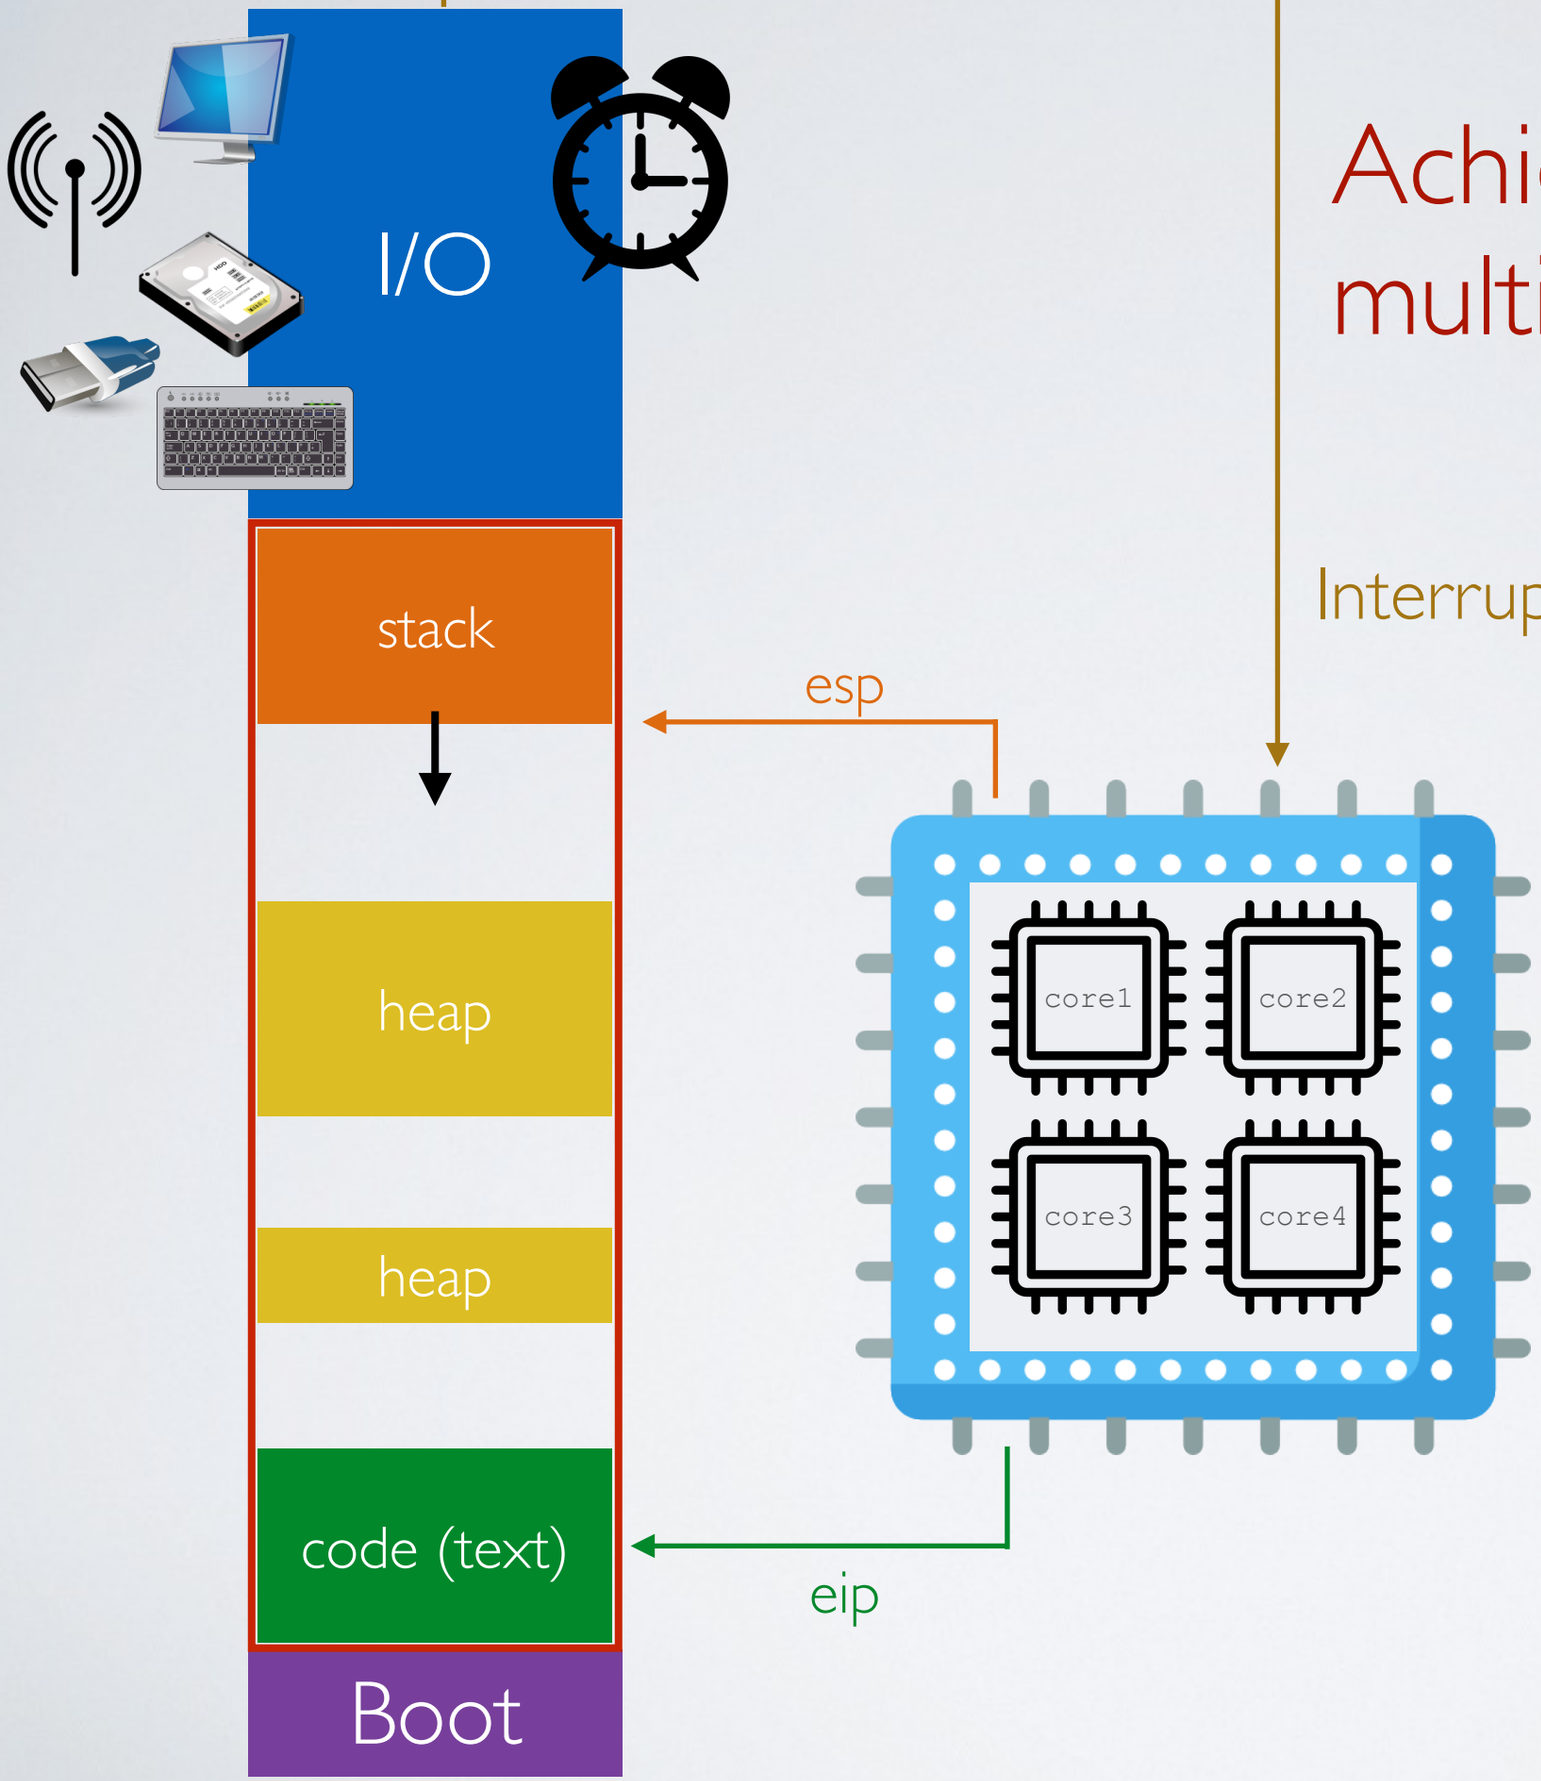
With concurrency

✓ **From the system perspective**
better CPU usage resulting in a faster execution overall
(but not individually)

✓ **From the user perspective**
programs are executed in parallel

➡ But it requires scheduling, synchronization and some protection mechanisms

Achieving parallelism with multi-core processors



Other problems that we are going to address during the semester

- **Scheduling**
  Decide which process to execute when severals are ready to be run

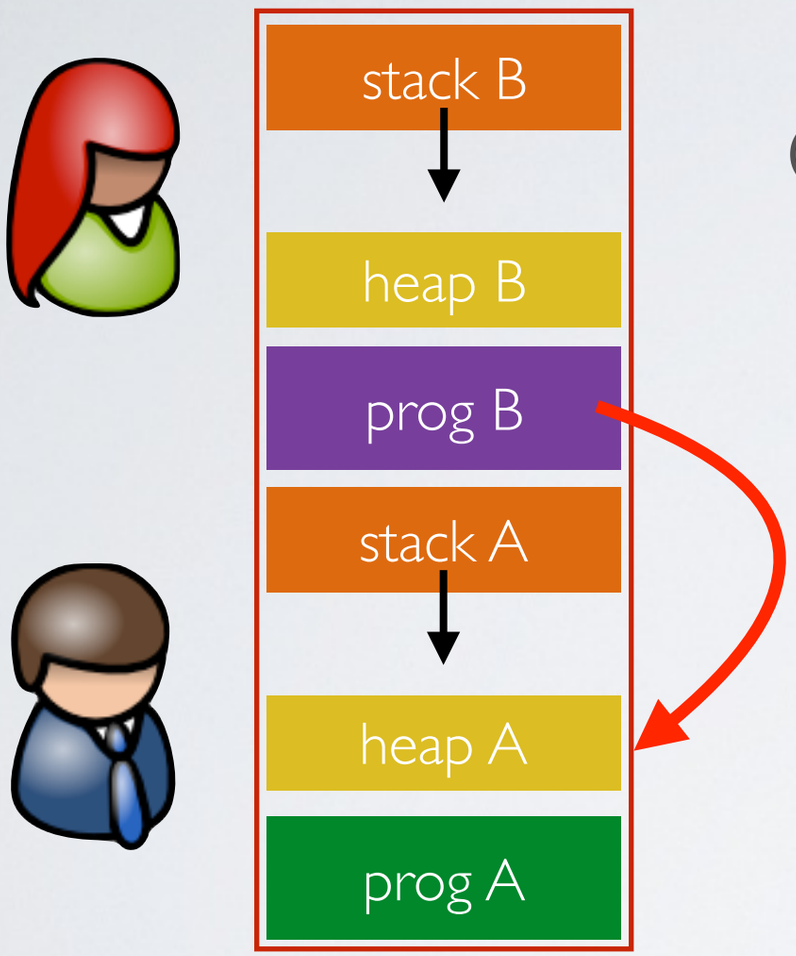
- **Synchronization**
  Manage concurrent access to resources using semaphores, locks, monitors

- **Communication**
  Exchange messages between processes using IPC (sockets & signals)

- **Threads**
  Lightweight concurrency within a process

The need for **user spaces**

An old problem from older constraints

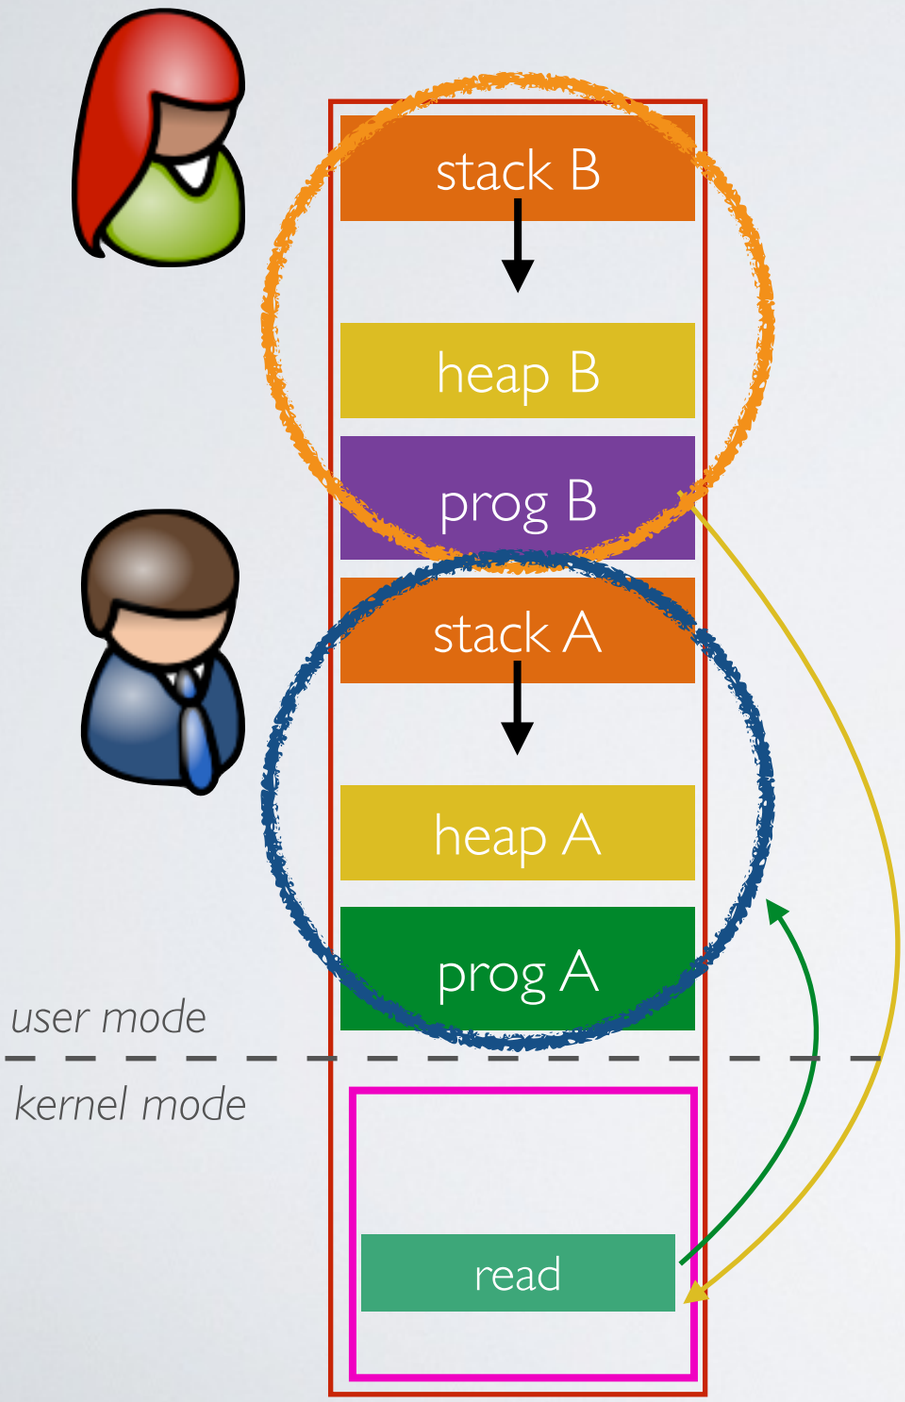


One computer and many users

Problem: what prevents Alice's from reading Bob's data?

- or start/stop any programs?
- or access any file on the filesystem
- or use any I/O device?
- or change the system configuration?
- or reboot the machine?

Definition of the user space



principle 1: user have full privileges with their own user space

principle 2: every access to another user space must go through the kernel via system calls (complete mediation)

principle 3: system calls can be allowed or denied based on the system security policy (access control)

Is multi-user paradigm obsolete?

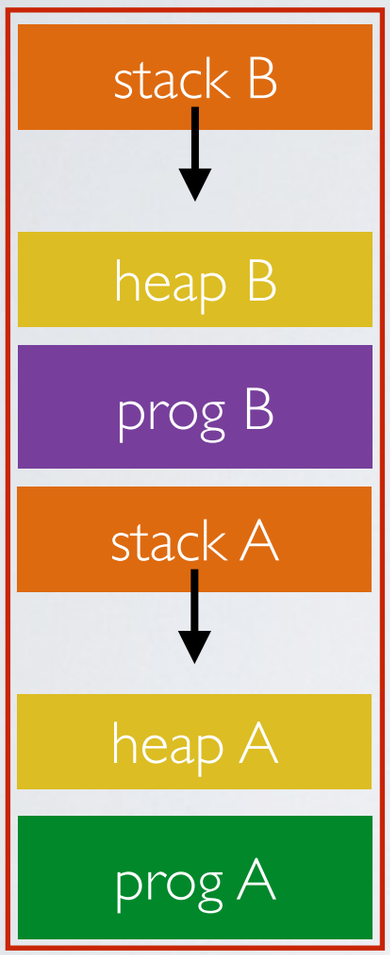
➡ Most servers, personal computers, mobile and embedded systems have a single physical user

◉ But not all programs are reliable nor trustworthy

✓ It is still a good model to provide **reliability** and **security**

The need for **virtual memory**

The problem of managing the memory



How to make programs and execution contexts co-exists in memory?

- ✓ Placing multiple execution contexts (stack and heap) at random locations in memory is not a problem ...
  ... well, as long as your have enough memory

- ◉ However having programs placed at random locations is problematic

Let's look at some C code and its binary

```c
#include <stdio.h>

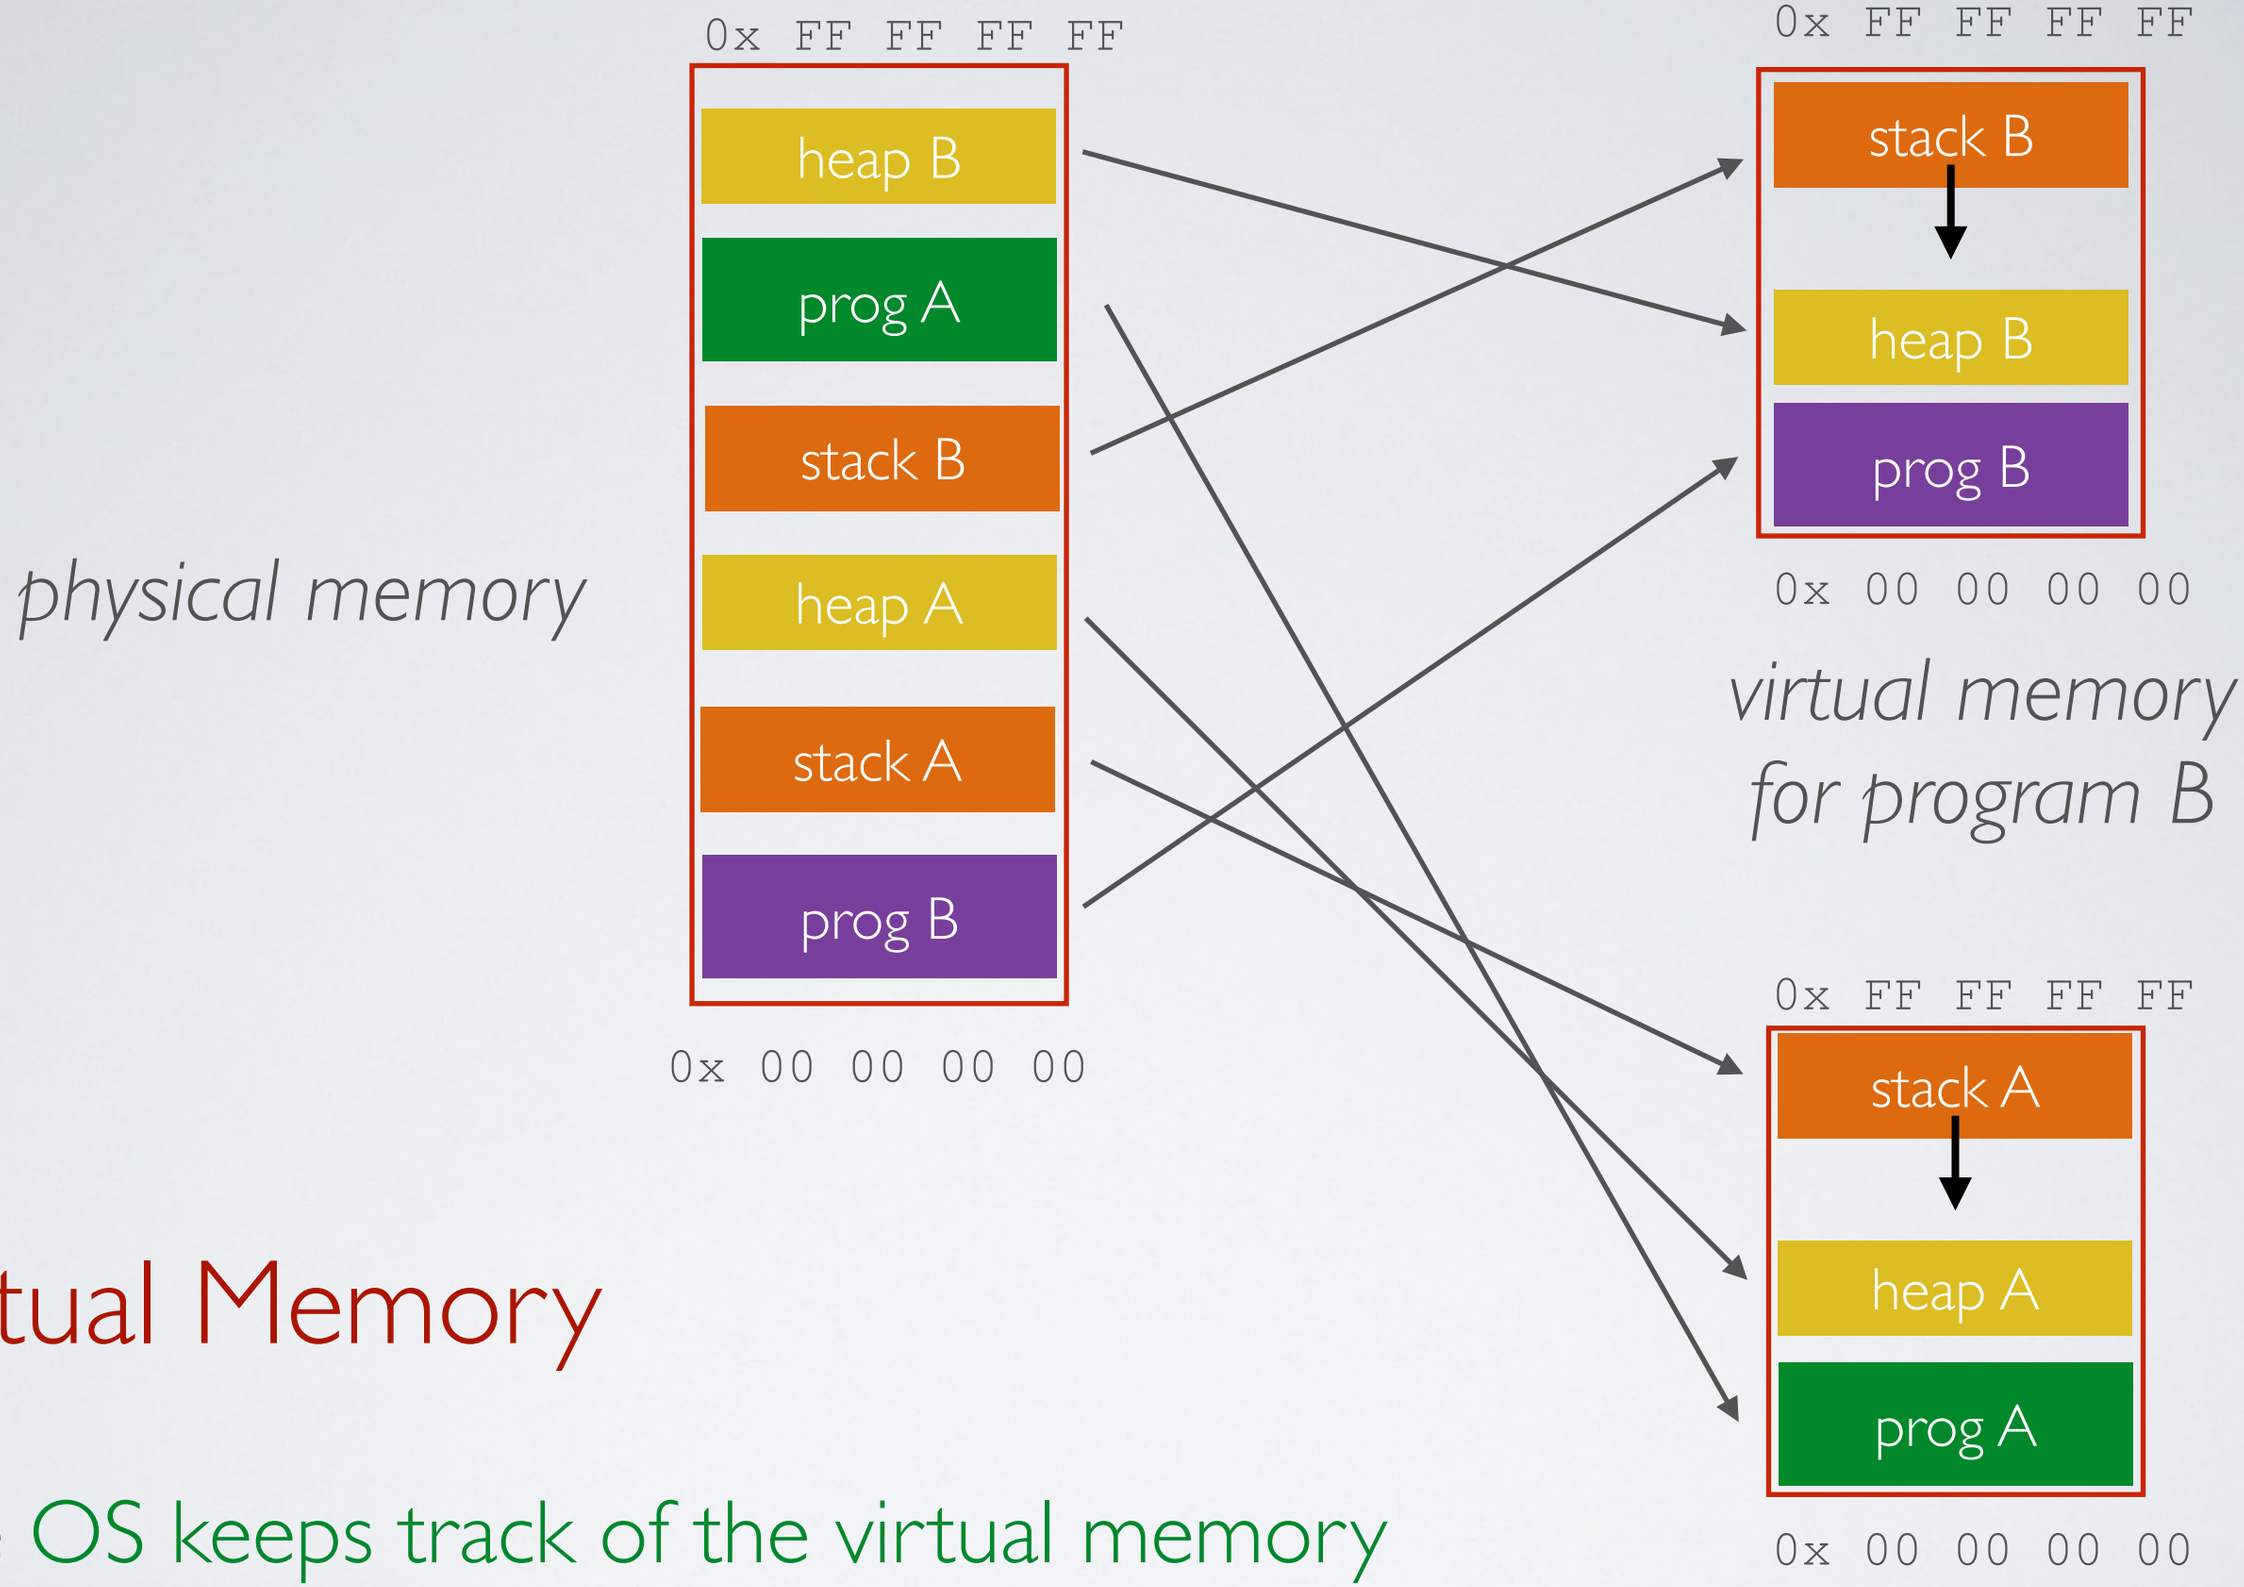
int foo(){
    printf("hello world!");
}

int main(int argc, char **argv){
    foo();
}
```

```
0804840b <foo>:
 804840b:   55                      push   ebp
 804840c:   89 e5                   mov    ebp,esp
 804840e:   83 ec 08                sub    esp,0x8
 8048411:   83 ec 0c                sub    esp,0xc
 8048414:   68 d0 84 04 08          push   0x80484d0
 8048419:   e8 c2 fe ff ff          call   80482e0 <printf@plt>
 804841e:   83 c4 10                add    esp,0x10
 8048421:   90                      nop
 8048422:   c9                      leave
 8048423:   c3                      ret

08048424 <main>:
 8048424:   8d 4c 24 04             lea    ecx,[esp+0x4]
 8048428:   83 e4 f0                and    esp,0xfffffff0
 804842b:   ff 71 fc                push   DWORD PTR [ecx-0x4]
 804842e:   55                      push   ebp
 804842f:   89 e5                   mov    ebp,esp
 8048431:   51                      push   ecx
 8048432:   83 ec 04                sub    esp,0x4
 8048435:   e8 d1 ff ff ff          call   804840b <foo>
 804843a:   b8 00 00 00 00          mov    eax,0x0
 804843f:   83 c4 04                add    esp,0x4
 8048442:   59                      pop    ecx
 8048443:   5d                      pop    ebp
 8048444:   8d 61 fc                lea    esp,[ecx-0x4]
 8048447:   c3                      ret
 8048448:   66 90                   xchg   ax,ax
 804844a:   66 90                   xchg   ax,ax
 804844c:   66 90                   xchg   ax,ax
 804844e:   66 90                   xchg   ax,ax
```

Since function addresses and others are hard-encoded in the binary, the program cannot be placed at random locations in memory



Virtual Memory

The OS keeps track of the virtual memory mapping table for each process and translates the addresses dynamically

Another problem

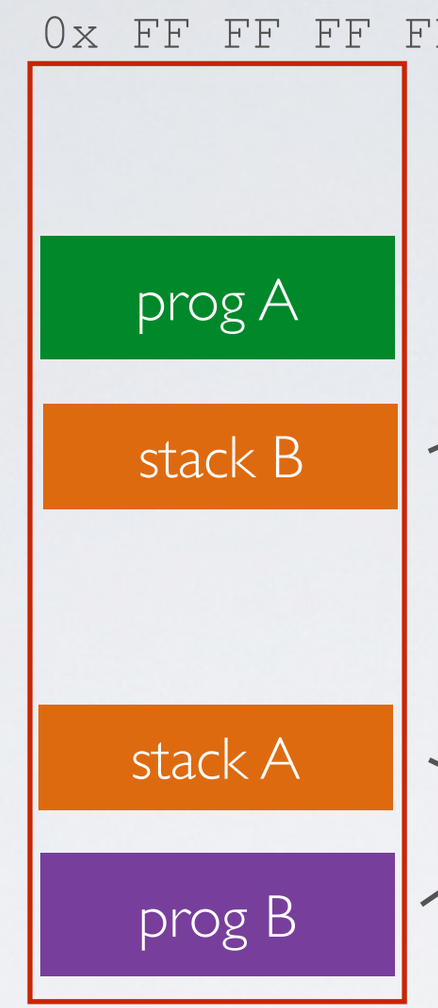
What if we run out of memory because of too many concurrent programs?

✓ Swap memory
move some data to the disk

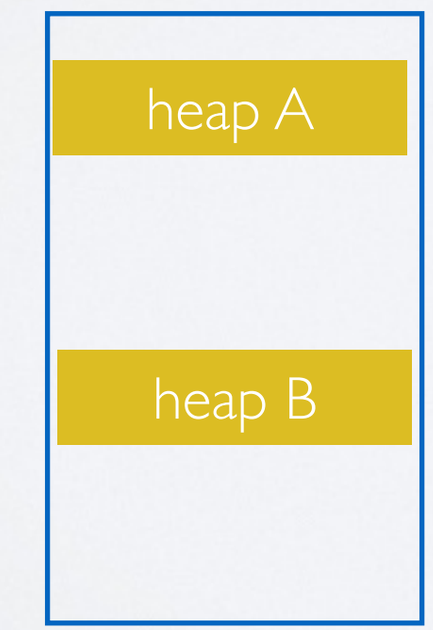
➡ Managing memory becomes very complex
but necessary

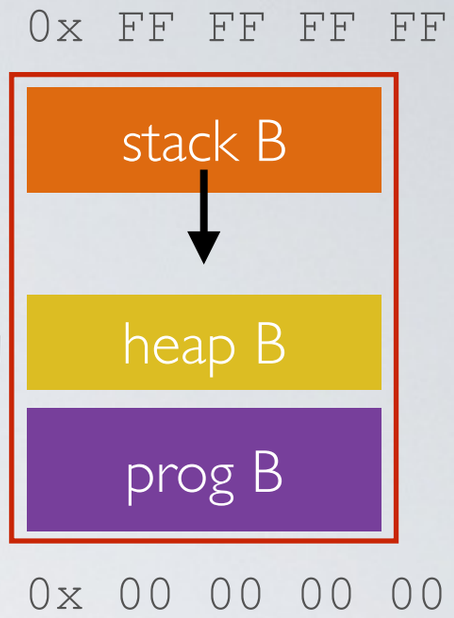
Swap

physical memory

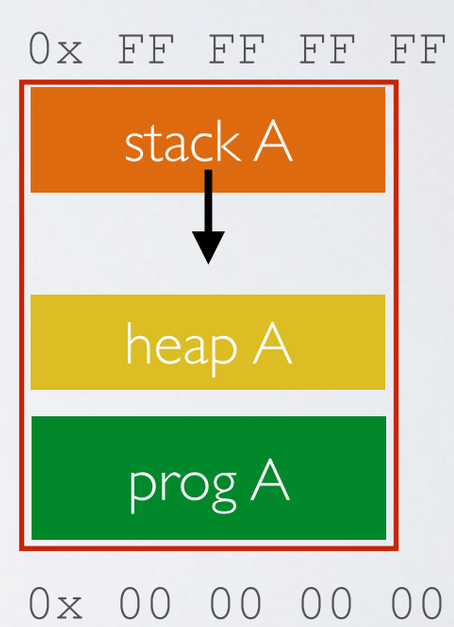


hard drive





virtual memory for program B



virtual memory for program A

The need for a **file system**

Files and Directories

versus

Reality

So, what is an **operating system**?

Operating System

➡ In a nutshell, an OS manages hardware and runs programs

- creates and manages processes
- manages access to the memory (including RAM and I/O)
- manages files and directories of the filesystem on disk(s)
- enforces protection mechanisms for reliability and security
- enables inter-process communication

For next week

- Read the book
- Read Pintos documentations
  (0-Introduction and A-Reference Guide)
- Work on Project 0
  (to be finalized in the next couple of days)
